# **Bovine Tumor Necrosis Factor Receptor-1 and Methods of Use**

## **CROSS REFERENCE TO RELATED APPLICATIONS**

5           This application claims priority under 35 U.S.C. §119(e) to U.S. provisional application serial number 60/122,156, filed February 26, 1999.

## **TECHNICAL FIELD**

          This invention relates to cytokines and cell signaling, and more particularly, to bovine tumor necrosis factor (TNF) receptor-I.

## **BACKGROUND**

10           Tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) is a pleiotropic cytokine, and is produced by activated macrophages/monocytes and lymphocytes. TNF- $\alpha$  is a potent mediator in inflammatory and immune responses, including the recruitment of leukocytes to injured tissues during bacterial and other microbial infections, and following stimulation with  
15   inflammatory substances. When present in excessive quantities, however, TNF- $\alpha$  is known to cause tissue injury, and has been implicated in the pathology associated with several inflammatory and autoimmune diseases.

          The biological effects of TNF are mediated through two distinct receptors, TNF-RI and TNF-RII (in humans, p55 and p75, respectively), which differ in sequence and molecular  
20   mass. TNF-RI is reported to be present at low levels in most, if not all, human cell types, and expression of the gene in humans can be upregulated by infection, interferons, and modulators of second messengers, such as phorbol esters. The extracellular portions of both receptors also exist in soluble forms, which are derived by proteolytic cleavage from the cell surface. The soluble TNF receptors retain the ability to bind TNF in solution. Activated  
25   cells often shed their TNF receptors, which can render the target cell less sensitive to the biological effects of TNF. Soluble TNF receptors have been identified in urine and sera from

healthy individuals, and have been shown to be elevated in some chronic diseases and following inoculation with agents that induce TNF- $\alpha$  release.

## SUMMARY

5       The present invention describes the cloning and characterization of nucleic acid encoding the bovine tumor necrosis factor receptor-I (TNF-RI). Additionally, a soluble bovine TNF-RI was produced and demonstrated to be a potent inhibitor of bovine tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ). The availability of nucleic acid sequences encoding the bovine TNF-RI, particularly those nucleic acid sequences encoding a soluble form, provides a  
10   therapeutic compound for preventing and treating inflammatory diseases in bovine animals.

In general, the invention features an isolated nucleic acid, such as (a) the nucleotide sequence of SEQ ID NO:1; (b) a fragment of the nucleotide sequence of (a) encoding a functional polypeptide fragment; (c) a nucleotide sequence that is at least 85% identical to (a), or (b); or (d) a nucleotide sequence complementary to (a), (b) or (c). For instance, the  
15   nucleotide sequence may be at least 90% identical, or at least 95% identical, to (a) or (b). The nucleic acid may encode a bovine tumor necrosis factor receptor-I (TNF-RI), which may bind tumor necrosis factor (TNF). The nucleic acid may encode, for example, a TNF-RI having the amino acid sequence of SEQ ID NO:2.

The invention also features a nucleic acid such as (a) the nucleotide sequence shown  
20   in SEQ ID NO:3; (b) a fragment of the nucleotide sequence of (a) encoding a functional polypeptide fragment; (c) a nucleotide sequence that is at least 85% identical to (a) or (b); or (d) a nucleotide sequence complementary to (a), (b) or (c). The nucleic acid may encode a soluble bovine TNF-RI, which may bind TNF. The nucleic acid may encode, for example, a soluble bovine TNF-RI having the amino acid sequence of SEQ ID NO:4.

25       Additionally, there are provided vectors that include one or more of the above-described nucleic acids. The vector(s) may include elements necessary for expression of the above-described nucleic acids operably linked to the nucleic acid(s). The invention further provides host cells containing such vectors.

The invention also features isolated bovine TNF-RI and soluble bovine TNF-RI  
30   polypeptides. Additionally, antibodies that have specific binding affinity for the bovine

TNF-RI and soluble bovine TNF-RI polypeptides are provided. A feature of the invention is a soluble bovine TNF-RI, which may include a bovine TNF-RI extracellular domain or fragments thereof. The soluble bovine TNF-RI may further bind TNF.

Yet another feature of the invention is an isolated nucleic acid encoding a fusion  
5 protein. Within the context of the present invention, the fusion protein may be encoded by a nucleic acid encoding a soluble bovine TNF-RI and a second nucleic acid sequence. For example, the second nucleic acid sequence may be an antibody or fragment thereof.

The invention also features a method of inhibiting TNF cytotoxicity in a bovine animal, and includes administering an effective amount of a polypeptide or a nucleic acid  
10 encoding the polypeptide to the animal. In the context of the present invention, the polypeptide is one or more soluble, functional polypeptide fragments of bovine TNF-RI that bind TNF and thereby inhibit TNF cytotoxicity in the bovine animal. For example, soluble, functional polypeptide fragments of bovine TNF-RI may be administered by direct infusion, and further, may be directly infused into the animal's mammary gland. In the context of the  
15 present invention, inhibition of TNF cytotoxicity in the animal is useful, for example, to treat mastitis. The effective amount may be, for example, from about 1 µg/kg body weight to about 1 mg/kg body weight.

Another feature of the invention is a pharmaceutical composition, including one or more soluble, functional polypeptide fragments of bovine TNF-RI and a pharmaceutically  
20 acceptable carrier. Also provided is a kit, which includes at least one unit dose of the above-described pharmaceutical composition.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention  
25 pertains. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable, but not necessarily preferred, methods and materials are described below. In addition, the materials, methods and examples are illustrative only and not intended to be limiting. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in  
30 their entirety. In case of conflict, the present specification, including definitions, will control.

The details of one or more embodiments of the invention are set forth in the accompanying drawings and the description below. Other features, objects, and advantages of the invention will be apparent from the drawings and detailed description, and from the claims.

## DESCRIPTION OF DRAWINGS

Fig. 1 is the nucleotide sequence and the deduced amino acid sequence of a bovine tumor necrosis factor receptor-I (TNF-RI) cDNA (GenBank Accession No. U90937). A solid line indicates the hydrophobic signal peptide and a dashed line indicates the transmembrane region. Within the extracellular domain, the cysteine residues are circled and N-linked glycosylation sites are boxed.

Fig. 2 is a graph showing the presence of tumor necrosis factor (TNF) in bovine mammary gland prior to and following the onset of a febrile response to *Escherichia coli* challenge of one quarter of the mammary gland.

Fig. 3 is a graph demonstrating anti-bovine TNF cytotoxicity by soluble bovine TNF-RI.

Like reference symbols in the various drawings indicate like elements.

## DETAILED DESCRIPTION

The invention relates to a bovine tumor necrosis factor receptor-I (TNF-RI), and more specifically, a soluble bovine TNF-RI, which is a potent inhibitor of bovine TNF- $\alpha$ . This invention demonstrates that soluble bovine TNF-RI has therapeutic value as an inhibitor of tumor necrosis factor (TNF) in cattle suffering from coliform mastitis or other inflammatory disease.

## *Bovine TNF receptor-I*

In one aspect, the invention features an isolated nucleic acid encoding a bovine tumor necrosis factor receptor-I (TNF-RI), or the complement thereof. As used herein, "isolated" refers to a nucleotide sequence encoding part or all of the bovine TNF-RI, but free of sequences that normally flank one or both sides of nucleic acid sequences encoding bovine TNF-RI in the bovine genome. The term "TNF-RI" refers to a receptor in which the extracellular domain binds TNF and propagates a signal to the cell via the intracellular domain. Typically, TNF-RI is found on most, if not all, bovine cell types, including neutrophils and mononuclear leukocytes.

An example of a nucleotide sequence encoding a bovine TNF-RI is shown in Fig. 1 (SEQ ID NO:1), which is a 2440 bp cDNA having an open reading frame of 1413 nucleotides. The amino acid sequence of a bovine TNF-RI is shown in SEQ ID NO:2, and is 471 amino acids in length. The start codon for the bovine TNF-RI is a methionine corresponding to nucleotide 294 of SEQ ID NO:1 and the protein terminates with a stop codon corresponding to nucleotide 1709. The bovine TNF-RI includes a signal peptide, an extracellular domain, a transmembrane domain and an intracellular domain (Fig. 1).

In another aspect, the invention features a soluble fragment of the bovine TNF-RI, hereinafter referred to as "soluble TNF-RI" or "soluble bovine TNF-RI". As used herein, "soluble" TNF-RI refers to a TNF-RI polypeptide that is water-soluble or soluble in an aqueous solution, preferably having a physiological pH. An example of a nucleotide sequence encoding a soluble bovine TNF-RI is shown in SEQ ID NO:3 and is 543 nucleotides in length. An example of an amino acid sequence of a soluble bovine TNF-RI is shown in SEQ ID NO:4 and consists of 181 amino acids. SEQ ID NO:4 corresponds to the extracellular domain of the full-length bovine TNF-RI (Fig. 1). Typically, a soluble bovine TNF-RI includes the extracellular domain, but may include more or less amino acids, provided that the polypeptide remains soluble.

A bovine TNF-RI or soluble bovine TNF-RI nucleic acid may have a sequence that deviates from that shown in SEQ ID NO:1 or SEQ ID NO:3, respectively. For example, a nucleic acid sequence can have at least 85% sequence identity to the nucleotide sequence of SEQ ID NO:1 or SEQ ID NO: 3. In some embodiments, the nucleic acid sequence can have at

least 90% sequence identity or at least 95% sequence identity to SEQ ID NO:1 or SEQ ID NO:3.

Generally, percent sequence identity is calculated by determining the number of matched positions in aligned nucleic acid sequences, dividing the number of matched positions by the total number of aligned nucleotides, and multiplying by 100. A matched position refers to a position in which identical nucleotides occur at the same position in aligned nucleic acid sequences. Nucleic acid sequences can be aligned by visual inspection, or by using sequence alignment software, such as the Sequence Analysis Software Package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, WI 53705, or BLAST programs (provided as a service by the National Center for Biotechnology Information, [www.ncbi.nlm.nih.gov](http://www.ncbi.nlm.nih.gov)). The programs are described in detail by Karlin et al., *Proc Natl Acad Sci USA* 87:2264 (1990) and 90:5873 (1993), and Altschul et al., *Nucl Acids Res* 25:3389 (1997). Typically, default parameters and algorithms are used when performing sequence analysis. Sequence analysis of TNF-RI as described herein was performed using BestFit (with a Gap Weight of 5.0 and 3.0 and a Length Weight of 0.3 and 0.1 for nucleic acids and amino acids, respectively).

In another aspect, the invention includes fragments of the bovine TNF-RI nucleic acid and polypeptide. Fig. 1 shows various domains (*i.e.*, intracellular, transmembrane and extracellular) of the bovine TNF-RI nucleic acid and polypeptide that, by way of example, provide useful regions from which to generate fragments. For example, a fragment of a bovine TNF-RI nucleic acid sequence can include from about nucleotide 294 to about nucleotide 1709 of SEQ ID NO:1, from about nucleotide 378 to about nucleotide 923, from about nucleotide 924 to about nucleotide 1001 or from about nucleotide 1002 to about nucleotide 1709. Given the nucleotide sequence of a bovine TNF-RI, virtually any nucleic acid fragment can be generated by known means (*e.g.*, restriction enzyme digestion, the polymerase chain reaction) and, if so desired, expressed to produce the corresponding polypeptide fragment. Alternatively, the bovine TNF-RI polypeptide can be cleaved (*e.g.*, proteolytically) to generate polypeptide fragments directly.

Additionally, "functional polypeptide fragments" of the bovine TNF-RI can be produced. "Functional polypeptide fragments" are defined as polypeptide fragments of bovine

TNF-RI that retain the ability to bind bovine TNF. For instance, a polypeptide from about nucleotide 378 to about nucleotide 923 corresponding to the extracellular domain was demonstrated herein to retain the ability to bind TNF. Therefore, the polypeptide encoded by nucleotides 378-923 of SEQ ID NO:1 is an example of a functional polypeptide fragment. The ability of polypeptide fragments to bind TNF may be assayed using the methods described herein.

A nucleic acid encoding a bovine TNF-RI may be obtained from, for example, a cDNA library made from bovine endothelial cells treated with TNF, or can be obtained by other means, including, but not limited to, the polymerase chain reaction (PCR). PCR refers to a procedure or technique in which target nucleic acids are amplified. PCR can be used to amplify specific sequences from DNA as well as RNA, including sequences from total genomic DNA or total cellular RNA. Various PCR methods are described, for example, in *PCR Primer: A Laboratory Manual*, Dieffenbach, C. & Dveksler, G., Eds., Cold Spring Harbor Laboratory Press, 1995. Generally, sequence information from the ends of the region of interest or beyond is employed to design oligonucleotide primers that are identical or similar in sequence to opposite strands of the template to be amplified. Representative oligonucleotide primers are shown in SEQ ID NO:5, 6, 7 and 8.

Furthermore, bovine TNF-RI nucleic acids can be detected by, for example, a variety of hybridization techniques. Hybridization typically involves Southern or Northern blotting (see, for example, sections 9.37-9.52 of Sambrook et al., 1989, *"Molecular Cloning, A Laboratory Manual"*, 2<sup>nd</sup> Edition, Cold Spring Harbor Press, Plainview; NY). Oligonucleotide fragments can hybridize under moderate stringency conditions, or preferably, under high stringency conditions to a bovine TNF-RI nucleic acid (e.g., DNA or RNA), or the complement thereof. High stringency conditions can include the use of low ionic strength and high temperature washes, for example 0.015 M NaCl/0.0015 M sodium citrate (0.1X SSC), 0.1% sodium dodecyl sulfate (SDS) at 65°C. Alternatively, denaturing agents such as formamide can be employed during hybridization (e.g., 50% formamide with 0.1% bovine serum albumin/0.1% Ficoll/0.1% polyvinylpyrrolidone/50 mM sodium phosphate buffer at pH 6.5 with 750 mM NaCl, 75 mM sodium citrate at 42°C).

### *Bovine TNF receptor-I nucleic acid constructs*

The present invention includes vectors containing the bovine TNF-RI nucleic acid of SEQ ID NO:1 (or the complement thereof), nucleic acids encoding functional polypeptide fragments of SEQ ID NO:1 (*e.g.*, SEQ ID NO:3) (or the complements thereof) and nucleic acids having at least 85% sequence identity to SEQ ID NO:1 (or the complements thereof). Cloning vectors and expression vectors suitable for use in the present invention are commercially available and used routinely by those of skill in the art. Vectors of the invention may additionally comprise elements necessary for expression operably linked to a bovine TNF-RI nucleic acid sequence. Elements necessary for expression include promoter sequences, and additionally may include regulatory elements, such as enhancer sequences, response elements or inducible elements that modulate expression of the bovine TNF-RI nucleic acid sequence. As used herein, "operably linked" refers to positioning of a promoter and/or other regulatory element(s) in a construct relative to the bovine TNF-RI nucleic acid sequences in such a way as to direct or regulate expression of the TNF-RI nucleic acid. Such constructs can be produced by recombinant DNA technology methods routine in the art.

In still another aspect, the invention features nucleic acid sequences encoding a fusion protein containing a soluble bovine TNF-RI and a second polypeptide. The second polypeptide may be an antibody or fragment thereof. As used herein, "antibody" refers to whole antibodies of any class, *i.e.*, IgG, IgA, IgM or any other known class and includes portions or fragments of whole antibodies (*e.g.*, Fab fragments) having the desired affinity.

The choice of expression systems depends upon several factors, including, but not limited to, replication efficiency, selectability, inducibility, targeting, the level of expression desired, ease of recovery and the ability of the host to perform post-translational modifications. For instance, the high cysteine content found in the TNF-RI proteins has previously created solubility problems due to improper protein folding when the receptors are expressed in prokaryotic expression hosts (Jones et al., 1997, *Biochemistry* 36:14914-14923, and references therein). The *Pichia pastoris* heterologous gene expression system, on the other hand, has been used successfully to produce large quantities of TNF-RI in a soluble form that have previously been insoluble when expressed in *E. coli*. Using a *Pichia pastoris* expression system, soluble bovine TNF-RI was expressed as a diffuse polypeptide ranging in

molecular weight from ~20-25 kDa, each band probably representing a different level of glycosylation of the polypeptide. However, despite producing variously glycosylated polypeptide species, *P. pastoris* has been reported to not hyperglycosylate secreted proteins, which is especially important for proteins that are intended for *in vivo* use (Tschopp et al., 1987, *BioTechnology* 5:1305-1308).

As used herein, the term "host" or "host cell" is meant to include not only prokaryotes, such as *E. coli*, but also eukaryotes, such as yeast, plant and animal cells. A host cell can be transformed or transfected with a DNA molecule (*e.g.*, a vector) using any of the techniques commonly known to those of ordinary skill in the art. Host cells containing a vector of the present invention may be used for such purposes as propagating the vector, producing bovine TNF-RI nucleic acid (*e.g.*, DNA, RNA, antisense RNA) or expressing the bovine TNF-RI, soluble forms thereof and other functional polypeptide fragments.

Nucleic acids of the present invention may be detected by methods such as Southern blot or Northern blot analysis (*i.e.*, hybridization), polymerase chain reaction (PCR) or *in situ* hybridization analysis. TNF-RI proteins are typically detected by Western blot analysis (using antibodies (monoclonal or polyclonal) that have specific binding affinity for a bovine TNF-RI polypeptide) or sodium dodecyl sulphate (SDS)-polyacrylamide gel electrophoresis followed by Coomassie Blue-staining.

#### *Therapeutic and diagnostic uses for bovine TNF receptor-I*

The invention also features novel therapeutic and diagnostic uses for the bovine TNF-RI nucleic acids and polypeptides of the present invention. For example, soluble, functional polypeptide fragments of TNF-RI (*e.g.*, soluble bovine TNF-RI, *e.g.*, the extracellular domain of TNF-RI) can be used to therapeutically treat bovine mastitis.

Mastitis is defined as inflammation of the mammary gland. Infectious mastitis is caused by a plethora of microbial agents (Watts, 1988, *Vet Micro* 16:41-66). Veterinarians are routinely called upon to treat cows for mastitis, and nearly half of the nation's herd of 9.5 million dairy cows in the US (USDA estimates for January, 1997) will experience at least one episode of mastitis during each lactation. As used herein, "lactation" refers to the period in which the mammary gland produces milk. Bovine lactation typically lasts approximately

305 to 365 days, followed by 45-60 days of a dry, non-lactating period (to allow, for example, mammary gland "regeneration of tissue" and colostrum formation). At the end of a dry period, a cow calves and begins the lactation cycle again.

Bovine coliform mastitis, characterized by inflammation of the mammary gland due to intramammary infections with gram negative bacteria, is common in dairy cattle during the periparturient and early lactation periods, and is a major cause of lost milk production and reduced milk quality for the dairy industry. Antibiotics play a limited role in treatment of mastitis (e.g., dry cow intramammary therapy or during lactation caused by gram positive bacteria, e.g., *Streptococcus* spp.), and control procedures mainly entail preventing exposure of teat canals to new infections. Antibiotics are ineffective against coliform (i.e., gram negative) bacterial infections, and therefore, there are no approved efficacious treatments for coliform mastitis.

Mastitis-induced hypogalactia is a major financial concern of dairy farmers. Hypogalactia is apparently mediated in part by local factors in the infected quarter of the mammary gland but also by systemic reactions that affect the non-infected quarters of the same mammary gland. Additionally, the problem of coliform mastitis is compounded by the fact that a significant number of intramammary infections with coliform bacteria result in a peracute disease, which is accompanied by severe systemic disturbances and often death.

When mastitis is induced by mammary gland challenge with *E. coli* or endotoxin, TNF is produced and detected in whey before or coincident with physiological (e.g., pyrexia), cellular (e.g., leukocytic influx), and mammary gland (e.g., hypogalactia) responses. Fig. 2 illustrates a temporal relationship between TNF and rectal temperature approximately 12 h after challenge with *E. coli*. Milk TNF- $\alpha$  levels and other inflammatory cytokines have been shown to be greatly elevated during natural or experimental bovine coliform mastitis, while extremely high serum TNF- $\alpha$  concentrations have been associated with acute and peracute coliform mastitis. Production of TNF appears consistently throughout the disease progression and the levels of TNF found in lacteal secretions typically correlate with the clinical severity of disease.

The cloning and sequencing of bovine TNF-RI nucleic acids, as disclosed herein, provides a necessary tool for the expression of soluble forms of bovine TNF-RI to block TNF

cytotoxicity locally in the bovine mammary gland. Soluble forms of the bovine TNF-RI polypeptide are also useful for the therapeutic treatment of other bovine inflammatory diseases. The efficacy of the soluble bovine TNF-RI as an inhibitor of TNF- $\alpha$  cytotoxicity is demonstrated herein. Additionally, evidence demonstrating that the soluble bovine TNF-RI is a better inhibitor of bovine TNF- $\alpha$  than monoclonal antibody (MAb) BC9 (an antibody directed towards TNF- $\alpha$ ) is significant, since anti-TNF- $\alpha$  monoclonal antibodies have been shown to elicit an anti-globulin response when used *in vivo* to neutralize TNF- $\alpha$  in humans (Abraham et al., 1998, *Lancet* 351:929-933). Moreover, soluble bovine TNF-RI that binds both TNF- $\alpha$  and TNF- $\beta$  (lymphotoxin) is more valuable as an anti-TNF agent than antibodies that recognize only one or the other.

In one aspect of the present invention, there is provided a method of inhibiting TNF cytotoxicity in a bovine animal by administering an effective amount of one or more soluble, functional polypeptide fragments of bovine TNF-RI (or one or more nucleic acids encoding soluble, functional polypeptide fragments of bovine TNF-RI) to the animal. The soluble, functional polypeptide fragments of bovine TNF-RI bind TNF and thereby inhibit TNF cytotoxicity. As used herein, "cytotoxicity" refers to cellular toxicity, which is typically measured by cell staining (*e.g.*, healthy cells may exclude a certain dye, whereas dying or dead cells absorb the dye). The routes of administration can depend on a variety of factors, such as the type and location of the infection. It is anticipated that the preferred therapeutic use for soluble, functional polypeptide fragments of bovine TNF-RI are administration of the soluble, functional polypeptide fragment(s) directly into the mammary gland to treat mastitis in the affected quarter(s). Typically, infusion into the mammary gland is via the teat canal. This method of administration (via an infusion tube) is currently performed by dairy farm employees to introduce antibiotics directly into the mammary gland. More general routes of administration, such as intravenous, intramuscular, intraperitoneal, intrauterine, intravaginal, intranasal, intradermal, subcutaneous, topical, or the like are also provided.

A preparation containing at least one soluble, functional polypeptide fragment of bovine TNF-RI can be in any form, provided the preparation can be administered to a bovine animal in an amount and for a duration that is effective to prevent, reduce, and/or eliminate bovine mastitis or other inflammatory disease. For example, preparations of soluble,

functional polypeptide fragments of bovine TNF-RI for administration can include solutions, suspensions, emulsions, gels, ointments, creams, powders, pills, capsules and tablets. In addition, preparations within the scope of the invention can contain additional ingredients, including, without limitation, pharmaceutically acceptable aqueous, non-aqueous, and solid  
5 vehicles or carriers, therapeutic compounds, steroids, mucolytic agents, other anti-inflammatory agents, immunosuppressants, vasodilators, vasoconstrictors, and/or combinations thereof.

The dosages of soluble, functional polypeptide fragments of bovine TNF-RI depends upon many factors, including the mode of administration and the degree of treatment  
10 required (*e.g.*, whether the infection is confined to the mammary gland or has become systemic). Typically, the concentration of soluble, functional polypeptide fragments of bovine TNF-RI contained within a single dose will be an amount that effectively reduces TNF levels without inducing significant toxicity. Generally, a preparation may be infused into the mammary gland in a volume of from about 5 ml to about 30 ml, and may include, by,  
15 way of example, a dose of from about 10 mg to about 100 mg of soluble, functional polypeptide fragments of bovine TNF-RI. Administered doses of soluble, functional polypeptide fragments of bovine TNF-RI may be lower if, for instance, the soluble, functional polypeptide fragments of bovine TNF-RI are expressed as a fusion protein that ultimately results in an increased binding affinity by the soluble, functional polypeptide  
20 fragments for TNF. Infusion regimens for the soluble, functional polypeptide fragments of bovine TNF-RI may include, but are not limited to, the first 2-3 milkings after mastitis is initially recognized in an animal.

The invention will be further described in the following examples, which do not limit  
25 the scope of the invention described in the claims.

### Example 1—Cloning the nucleic acid sequences encoding the bovine tumor necrosis factor receptor-I (TNF-RI)

The following primers were designed for polymerase chain reaction (PCR) amplification from conserved regions among the porcine TNF-RI cDNA:

5 forward primer: 5'-AGTGTGTGTCCCCAAGGAAA-3' (SEQ ID NO:5) and  
reverse primer: 5'-GCAGCCACACACGGTGTCC-3' (SEQ ID NO:6). A Uni-ZAP™ XR  
cDNA library (Stratagene, La Jolla, CA) of bovine endothelial cells treated with recombinant  
human TNF- $\alpha$  (rhuTNF- $\alpha$ ) was titered, diluted, and used as template for PCR. A 250 bp  
PCR fragment was amplified from  $1.4 \times 10^3$  plaque-forming units (pfu). The DNA fragment  
10 was sequenced and showed high homology with porcine and human TNF-RI sequences.  
This fragment was labeled with  $^{32}\text{P}$ -dCTP using the random priming method (Pharmacia,  
Piscataway, NJ) and then used as a probe to screen the bovine endothelial cell cDNA library.

Plaque lifts and phagemid *in vivo* excision were carried out according to  
manufacturer's protocols. In short,  $1.4 \times 10^4$  pfus were plated. Plaque hybridization was  
15 performed overnight at 42°C in a solution containing 50% formamide, 6X SSC, 3.3X  
Denhardt's solution, 0.1 mg/ml sonicated salmon sperm DNA, and 0.4% SDS. Filters were  
washed twice in 2X SSC/0.1% SDS for 5 min at room temperature (RT), once in 1X  
SSC/0.1% SDS for 5 min at RT, once in 0.1X SSC/0.1% SDS for 5 min at RT, and a final  
wash in 0.1X SSC/0.1% SDS for 5 min at 53°C, then exposed at -70°C for 18 h to X-ray film  
20 for autoradiography. Positive plaques were amplified and re-screened. After the second  
screening, the double-positive  $\lambda$  clones were subjected to *in vivo* excision. The pBluescript  
phagemids excised from the  $\lambda$  clones were purified and insert sizes were evaluated by  
restriction enzyme digestion analysis. One of three positive clones, containing a cDNA  
insert that was approximately 2.5 Kb, was selected for further characterization.

25

### Example 2—Characterization of bovine TNF-RI

Double-stranded DNA sequencing was performed by automated dideoxy sequencing  
at the Iowa State University DNA Sequencing Facility. DNA and deduced amino acid  
sequences were analyzed using the programs in the GCG software package (University of  
30 Wisconsin Genetics Computer Group, Inc., Madison, WI, USA).

The composite cDNA sequence for the bovine TNF-RI coding region (Fig. 1) shows 82% homology with porcine TNF-RI and 77% homology with human TNF-RI. The deduced amino acid sequence for bovine TNF-RI shows 75% and 67% identity with porcine and human TNF-RI, respectively. The bovine TNF-RI amino acid sequence (Fig. 1) consists of a hydrophobic signal peptide (29 amino acids), a cysteine-rich extracellular domain (181 amino acids), a hydrophobic transmembrane region (23 amino acids), and a cytoplasmic tail (238 amino acids). The extracellular domain contains three potential N-glycosylation sites at the same positions as the porcine and human TNF-RI. Furthermore, the extracellular region contains 24 cysteine residues (4 repeated cysteine-rich domains), which are 100% conserved in all species and are consistent with belonging to the TNF receptor family.

Expression of TNF-RI in selected bovine cells and tissues was evaluated by Northern blot analysis. Mononuclear cells (MNC) and neutrophils were separated (Kehrli et al., 1990, *Am. J. Vet. Res.* 51:1826-1836; Harp et al., 1991, *Vet. Immunol. Immunopathol.* 28:29-35) and stimulated with pokeweed mitogen for 18 h (PWM; 10 µg/ml) and platelet activating factor for 3 h (PAF; 1 µg/ml), respectively. Lymph node and spleen were homogenized and RNA was extracted without stimulating the cells. Total RNA from cells and tissues was extracted using Trizol (Gibco BRL, Gaithersburg, MD) and chloroform, precipitated with isopropanol, and washed with 75% ethanol. Twenty µg of total RNA from each sample were electrophoresed through a 1% agarose gel containing formaldehyde, blotted onto nylon membranes, and probed with a <sup>32</sup>P-dCTP random labeled cDNA probe derived from bovine TNF-RI (~1.3 kb of the coding region). Prehybridization, hybridization, and washing conditions were the same as those used for the cDNA library screening.

Detectable expression of TNF-RI mRNA was found in bovine spleen and lymph node tissue, as well as blood mononuclear cells and neutrophils. The size of the transcript detected (~2.4 kb) is consistent with the predicted size of the mRNA derived from the cloned cDNA. These data confirm that the TNF-RI gene is present and expressed in bovine cells of immune lineage.

### Example 3—Expression and purification of soluble bovine TNF-RI

The sequence encoding the putative extracellular domain of bovine TNF-RI was amplified by PCR from the cloned bovine TNF-RI cDNA (Lee et al., 1998, *Vet. Immunol. Immunopathol.* 61:379-385) using an upstream primer (5'-

- 5 TCTCTCGAGAAAAGAGAGGCTGAAGCTCTGGTCCCTCACCCCGGG-3'; SEQ ID NO:7) and downstream primer (5'-  
GCTCTAGAGCTTATGTAGTGCCTGGGTCCTGAGAGTCTT-3'; SEQ ID NO:8). The 5' region of the upstream primer contains the last 27 nucleotides of the sequence coding for  $\alpha$ -factor signal peptide from the pPICZ $\alpha$  A vector (Invitrogen, San Diego, CA, USA), and  
10 incorporates an *Xho*I restriction site at the 5' end of the amplified product. The downstream primer incorporates a transcription stop codon and an *Xba*I restriction site at the 3' end of the amplified product.

- The amplified product was isolated using the Wizard® PCR Preps DNA Purification System kit (Promega, Madison, WI, USA), digested with *Xho*I and *Xba*I restriction  
15 endonucleases (Gibco BRL, Grand Island, NY, USA) and ligated into the *Xho*I and *Xba*I-sites of the pPICZ $\alpha$  A vector to produce pPICZ $\alpha$ /soluble TNF-RI. Ligations were transformed into *E. coli* strain Top10F' (Invitrogen) and transformants selected according to recommended procedure (Invitrogen). Recombinant clones were analyzed for the presence of insert by restriction digestion, and sequenced to confirm the integrity of the constructs.

- 20 *Sac*I-linearized pPICZ $\alpha$  plasmid DNA containing nucleic acid sequences encoding the soluble bovine TNF-RI (5 mg/transformation) was used to chemically transform *P. pastoris* strains GS115 and KM71 (Invitrogen) according to the Easy Comp™ *Pichia* transformation kit protocol (Invitrogen). Integration of vector DNA into the *Pichia* genome was confirmed by PCR using 5'AOX1 and 3'AOX1 primers as described in the  
25 EasySelect™ *Pichia* Expression Kit protocols (Invitrogen). The methanol utilization (Mut) phenotypes of Zeocin-resistant (Invitrogen) transformants from the GS115 transformation reaction were also analyzed according to the EasySelect™ *Pichia* Expression Kit protocols.

- Expression of soluble bovine TNF-RI was performed in baffled shake flasks (Sigma, St. Louis, Mo, USA) according to recommended procedure (EasySelect™ *Pichia* Expression  
30 Kit protocols). Buffered glycerol-complex medium (BMGY) was used for the generation of

biomass and buffered methanol-complex medium (BMMY) for induction of protein expression. To maintain induction, 100% methanol was added to a final concentration of 1% every 24 h. To purify the soluble bovine TNF-RI, *Pichia* culture supernatants were concentrated using Centricon Plus-80 concentrators (Millipore, Bedford, MA, USA) and dialyzed overnight at 4°C against column equilibration buffer (10 mM Tris-HCl, 25 mM NaCl, 10 mM β-mercaptoethanol, pH 8.0). They were then loaded onto 20 ml columns of diethylaminoethyl (DEAE)-sephacel (Sigma) previously equilibrated in the same buffer. Bound proteins were eluted using a NaCl gradient (0-500 mM) in 10mM Tris-HCl, pH 8.0. Protein in each fraction was confirmed by monitoring absorbance at A<sub>280</sub>. Fractions containing soluble bovine TNF-RI were pooled, concentrated using a Centriprep-10 concentrator (Millipore) and stored at -70°C. Five hundred µl of culture supernatants were concentrated to 15 µl, and the entire volume loaded onto an SDS-PAGE for analysis of the *Pichia*-expressed soluble bovine TNF-RI polypeptide.

#### Example 4—TNF inhibition assays

TNF inhibition assays were performed as described in the CellTiter 96™ Non-Radioactive Cell Proliferation Assay ([www.Promega.com/tbs/tb112/tb112.html](http://www.Promega.com/tbs/tb112/tb112.html)) with slight modifications. Briefly, two-fold serial dilutions of soluble bovine TNF-RI or anti-bovine TNF-α monoclonal antibody (MAb) BC9 (courtesy of Dr. Jan Naessens, International Livestock Research Institute, Nairobi, Kenya) were incubated for 1 h at room temperature with equal volumes of bovine whey samples (Shuster et al., 1993, *Am. J. Vet. Res.* 54:80-85) from milk obtained from quarters that had been infused with lipopolysaccharide (LPS) from *Escherichia coli* serotype 055:B5 (Sigma, St. Louis, Mo, USA). The samples were then assayed in triplicate for cytotoxicity on WEHI 164 mouse fibrosarcoma cells (clone 13), seeded at a concentration of 3 x 10<sup>4</sup> cells/well in RPMI-1640 medium (Sigma) supplemented with 10% heat-inactivated fetal bovine serum (Hyclone Laboratories, Logan, UT) and 50 µg gentamicin/ml (Sigma). A recombinant murine TNF-α was used as a standard to calculate TNF-α cytotoxicity in the samples. Absorbances were read at a wavelength of 590 nm and corrected for background absorbances using a reference wavelength of 650 nm.

### Example 5—Therapeutic efficacy of soluble bovine TNF-RI

A DNA fragment (SEQ ID NO:3) encoding 181 aa of the predicted extracellular domain of bovine TNF-RI (SEQ ID NO:4) was amplified by PCR and cloned into the pPICZ $\alpha$ A expression vector downstream of the inducible alcohol oxidase1 (AOX1) gene promoter and in frame with the sequence coding for the  $\alpha$  factor signal peptide. The resulting pPICZ $\alpha$ /soluble TNF-RI construct was linearized at a unique *Sac*I site within the 5'AOX1 region and transformed into GS115 and KM71 cells leading to integration of the vector DNA into the corresponding region of the *Pichia* genome. Integration into the *Pichia* genome was confirmed by PCR, and the Mut phenotype of GS115 integrants determined by growth on minimal methanol histidine plates. Several Mut<sup>+</sup> GS115 integrants, as well as Mut<sup>S</sup> KM71 integrants, were tested for their ability to express soluble bovine TNF-RI in small-scale expression cultures, and clones that secreted a polypeptide of the expected size (~21 kDa) upon induction with methanol, as determined by sodium dodecyl sulfate-polyacrylamide gel electrophoresis with Coomassie Blue staining, were selected and used in large-scale protein expression studies. Expressed proteins were purified to greater than 95% purity by ion-exchange chromatography and verified to be of bovine origin by Western blotting using rabbit anti-bovine whole serum that had been adsorbed with horse and pig serum proteins.

Purified soluble bovine TNF-RI polypeptide was evaluated for its ability to block bovine TNF- $\alpha$  cytotoxicity on murine WEHI 164 cells (Fig. 3). Bovine whey samples prepared from milk obtained from quarters that had been infused with 25  $\mu$ g LPS/quarter served as source of bovine TNF- $\alpha$ . The anti-bovine TNF- $\alpha$  MAb, derived from hybridoma BC9 (Sileghem et al., 1992, *Hybridoma* 11:617-627), was used as a reference for TNF- $\alpha$  cytotoxicity blockade. Dilutions of soluble bovine TNF-RI were incubated for 1 h at 37°C with equal volumes of whey samples containing 6.4 U bovine TNF- $\alpha$ /ml. For a control, whey samples were mixed with equal volumes of medium or the anti-bovine TNF- $\alpha$  MAb, BC9. Fifty  $\mu$ l of the mixtures were added to WEHI 164 cells clone 13 and incubated for a further 20 h. 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) (Sigma) was added, the samples incubated for an additional 4 h, and the reactions stopped by addition of stop/solubilization solution. Samples were then left to stand overnight at room

temperature, and the conversion of MTT into a formazan product by surviving cells evaluated by measuring absorbance at 590 nm. The expressed soluble bovine TNF-RI blocked TNF- $\alpha$  cytotoxicity by 50% when used at a concentration of about 200  $\mu$ g/ml, and 97% when used at a concentration of 300  $\mu$ g/ml (Fig. 3). In contrast, MAb BC9 inhibited 85% of TNF- $\alpha$  cytotoxicity when used at a concentration of 900  $\mu$ g/ml. Compared to the anti-bovine TNF- $\alpha$  monoclonal antibody BC9, soluble bovine TNF-RI exhibited greater than 2-fold more potency at blocking bovine TNF- $\alpha$  than did the monoclonal antibody.

It is to be understood that while the invention has been described in conjunction with the detailed description thereof, the foregoing description is intended to illustrate and not limit the scope of the invention, which is defined by the scope of the appended claims. Other aspects, advantages, and modifications are within the scope of the following claims.
